Outline

- **The following subjects will be discussed:**
 - ❖ **Assessment of adjustments.**
 - ❖ **Definition of criteria to accept new central values of cross sections after adjustments.**
 - ❖ **Avoid compensation among different input data in the adjustments.**
 - ❖ **Validation of the “a priori” and use of the “a posteriori” covariance matrix.**
 - ❖ **Issues related to the presence of negative eigenvalues in the “a priori” covariance matrix.**

Adjustment Formulas

$G=(M_{EC} + SM_{\sigma} S^T)$: total integral covariance matrix

$$\chi^2 = (\sigma' - \sigma)^T M_{\sigma}^{-1} (\sigma' - \sigma) + (E - C)^T M_{EC}^{-1} (E - C)$$

The cross sections modifications that minimize the χ^2 and the associated “a posteriori” covariance matrix are:

$$\sigma' - \sigma = M_{\sigma} S^T G^{-1} (E - C)$$

$$M_{\sigma'} = M_{\sigma} - M_{\sigma} S^T G^{-1} S M_{\sigma}$$

The χ^2 after adjustment is computed as:

$$\chi'^2 = (E - C)^T G^{-1} (E - C)$$

Assessment of Adjustments

- The first step is to select a comprehensive set of experiments, possibly complementary in the type of information that they provide.

- ❖ First criterion is given by the representativity factor:

$$f_{re} = \frac{(S_R M_\sigma S_E)}{[(S_R M_\sigma S_R)(S_E M_\sigma S_E)]^{1/2}} \quad \Delta R'^2 = \Delta R^2 (1 - f_{re}^2)$$

- ❖ The complementarity of the experiments can be established by looking at the correlation factor among the selected experiments (i. e. S_R is replaced by S_E of the experiment E').
- ❖ Experiments can be selected, because they provide information of elemental type to improve specific reactions (e. g. capture in irradiation experiment), or specific energy range of a cross sections (e. g. using particular detectors for spectral indices of threshold reactions).

Parameters for Assessing Adjustments

- **Adjustment Margin:** $AM^i = U_{\sigma}^i + U_{EC}^i - |(E^i - C^i)|$
- **Individual χ_i measured in sigmas (before adj.):** $\chi^i = \frac{|E^i - C^i|}{\sqrt{U_{\sigma}^i + U_{EC}^i}}$
- **Diagonal χ_i measured in sigmas (after adj.):** $\chi_{diag}^{i2} = (E^i - C^i)^2 G_{ii}^{-1}$
- **Initial χ^2 and χ_i^2 experiment contribution to χ^2 :** $\chi_{con}^{i2} = \frac{[(E - C)^T G^{-1}]_i \cdot (E^i - C^i)}{N_E}$
- **IS (Ishikawa factor):** $IS^i = \frac{U_{\sigma}^i}{U_{EC}^i}$
- **$\Delta \chi_{iE}^2$ contribution to $[\chi'^2 - \chi^2]$ due to change of (E-C):**

$$\Delta \chi_{iE}^2 = \frac{-[\Delta(E - C)^T M_{EC}^{-1}]_i \cdot \Delta(E^i - C^i)}{N_E}$$
- **$\Delta \chi_{i\sigma}^2$ contribution to $[\chi'^2 - \chi^2]$ due to $\Delta \sigma_i$:** $\Delta \chi_{i\sigma}^2 = \frac{-[\Delta \sigma^T M_{\sigma}^{-1}]_i \cdot \Delta \sigma_i}{N_E}$

Acceptance of Adjusted Central Values

After an adjustment is performed, are all cross section changes to be accepted (especially when large variations of cross sections are observed)? Several considerations:

- ❖ Sometimes the cross section changes are completely unphysical.
- ❖ Reject cross sections which variation is larger than one sigma of the “a priori” standard deviation.
- ❖ Caution has to be taken when large variations are observed in energy ranges that were not the main target of the adjustment.
- ❖ Caution also has to be exerted, when large variations of the cross sections are produced but the “a posteriori” associated standard deviation reductions are small.
- ❖ A good check, after adjustment, is to compare against existing validated files. A further action consists to compare the obtained adjusted cross sections against reliable differential data (require interactions with evaluators).

Acceptance of Adjusted Central Values

Unphysical cross section changes obtained in the adjustment.

Cross Section	Energy Group	Relative Change Due to Adjustment (%)
$^{238}\text{Pu } \sigma_{\text{capt}}$	3	-155.5
$^{238}\text{Pu } \sigma_{\text{capt}}$	10	-108.0
$^{238}\text{Pu } \sigma_{\text{capt}}$	16	-126.3
$^{238}\text{Pu } \sigma_{\text{capt}}$	17	-111.5

Acceptance of Adjusted Central Values

Cross sections with changes after adjustment larger than initial standard deviation

Cross Section	Energy Group	Relative Change Due to Adjustment (%)	Stand. Deviat. Before Adjustment (%)
$^{16}\text{O } \sigma_{\text{elas}}$	6	2.5	2.0
$^{56}\text{Fe } \sigma_{\text{elas}}$	8	14.2	10.5
$^{235}\text{U } \sigma_{\text{elas}}$	5	6.1	5.0
$^{238}\text{U } \sigma_{\text{fiss}}$	4	0.60	0.57
$^{239}\text{Pu } \sigma_{\text{capt}}$	15	12.6	7.9
$^{238}\text{Pu } \sigma_{\text{capt}}$	9	-61.4	31.0
$^{241}\text{Am } \sigma_{\text{fiss}}$	6	-1.8	1.3
$^{133}\text{Cs } \sigma_{\text{capt}}$	9	19.4	14.0
$^{105}\text{Pd } \sigma_{\text{capt}}$	11	32.2	12.7
$^{101}\text{Ru } \sigma_{\text{capt}}$	13	-16.0	9.0
$^{242}\text{Cm } \sigma_{\text{capt}}$	13	184.2	100

Acceptance of Adjusted Central Values

Cross sections with significant changes after adjustment, but small standard deviation variation

Cross Section	Energy Group	Relative Change Due to Adjustment (%)	Stand. Deviat. Before Adjustment (%)	Stand. Deviat. After Adjustment (%)
$^{105}\text{Pd } \sigma_{\text{capt}}$	4	-12.8	25.3	24.8
$^{56}\text{Fe } \sigma_{\text{elas}}$	10	11.4	9.2	8.2
$^{239}\text{Pu } \sigma_{\text{capt}}$	6	10.7	20.5	19.7
$^{238}\text{Pu } \sigma_{\text{capt}}$	6	-23.8	28.0	27.3
$^{240}\text{Pu } \sigma_{\text{inel}}$	5	12.4	32.0	31.0
$^{240}\text{Pu } \chi$	1	14.2	89.9	89.6
$^{242\text{m}}\text{Am } \sigma_{\text{capt}}$	12	10.8	50.0	49.4

Avoiding Compensations

- In many cases, the adjustment can produce untrustworthy results in terms of adjusted cross sections, when some forms of compensation exist. Compensations can appear in different ways:
 - ❖ It is possible that some reactions compensate each other (e. g. ^{239}Pu χ and inelastic), because of missing experiments able to discriminate between the two parameters. There is a need for specific (preferably of elemental type) integral experiments:
 - irradiation experiments (for capture, (n,2n))
 - spectral indices (capture and fission)
 - “flat” adjoint flux reactivity experiments (to separate inelastic from absorption cross section)
 - neutron transmission or leakage experiments (mostly for inelastic cross sections)
 - reaction rate spatial distribution slopes (elastic, and inelastic)

Avoiding Compensations

- ❖ Other sources of compensations are missing isotopes in the adjustment and missing reactions in the covariance matrix:
 - fission spectrum
 - anisotropic scattering
 - secondary energy distribution for inelastic cross sections (multigroup transfer matrix)
 - cross correlations (reaction and/or isotopes)
- ❖ Underestimation or overestimation of well known reaction standard deviations (e. g. ^{239}Pu fission)

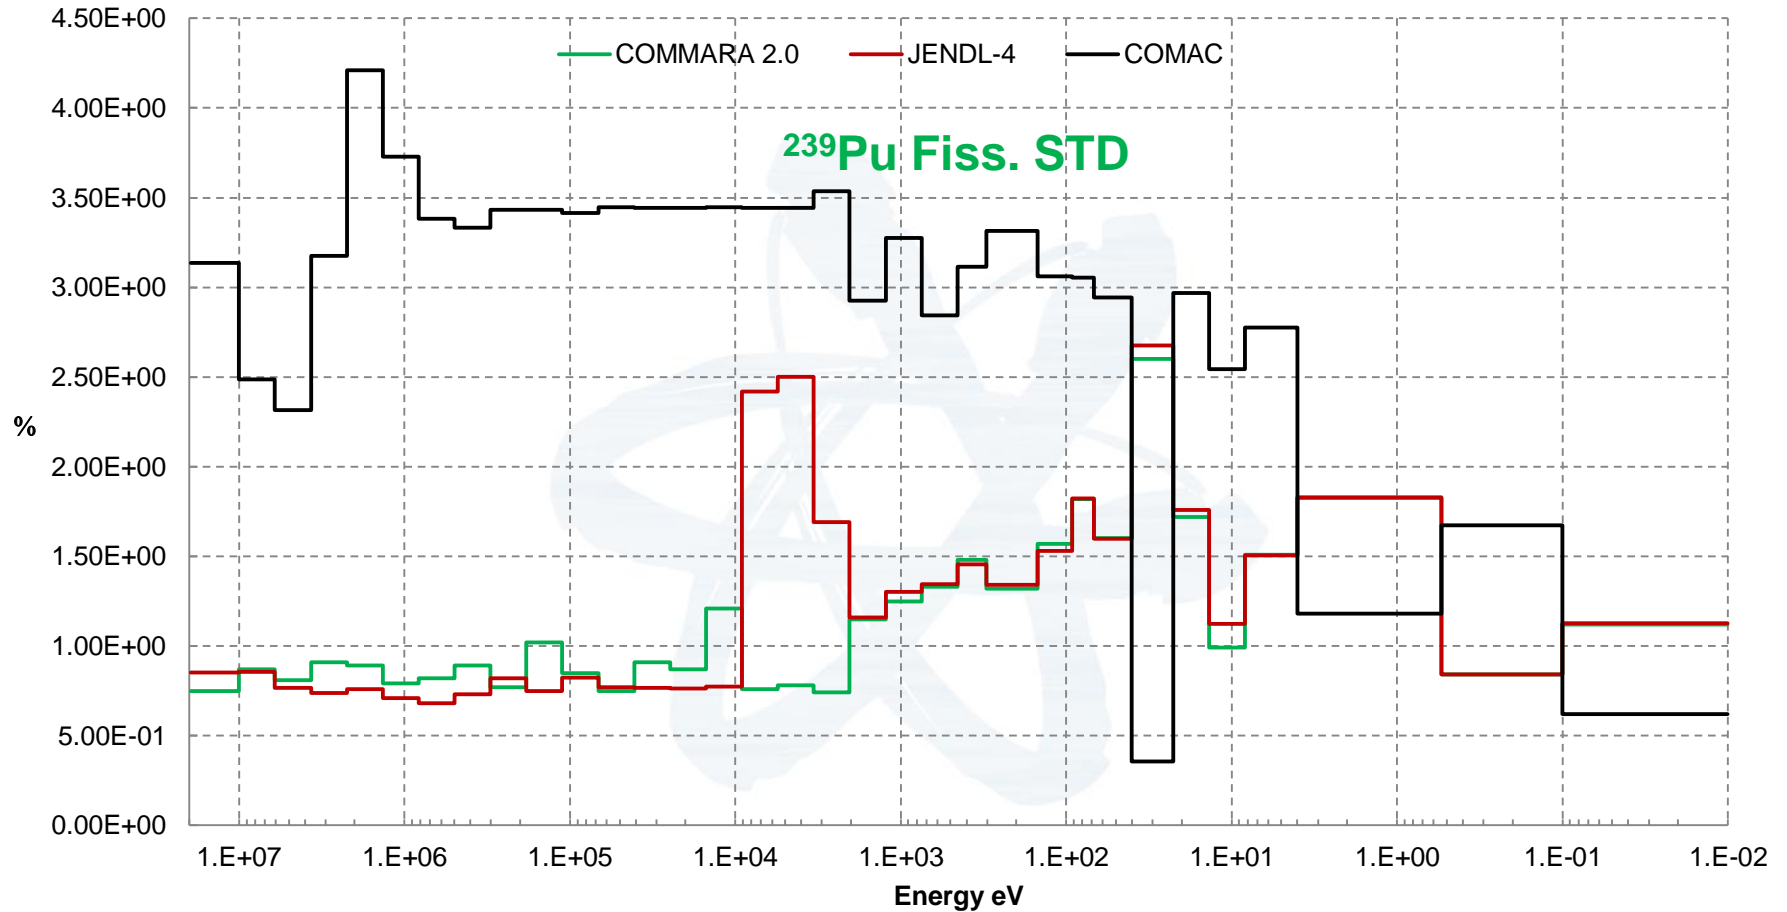

Avoiding Compensations

^{239}Pu σ_{fiss} standard deviations for different covariance matrix: COMMARA-2.0 (COMM.), COMAC, and JENDL-4 (JENDL) (%).

Avoiding Compensations

Covariance Matrix Validation

If the adjustment assessment has established that: experiments (with reliable experimental uncertainties and correlations) are useful, consistent and complementary, and sources of compensation have been identified and fixed, then we can identify problems with the covariance matrix:

- ❖ Presence of large (more than three sigmas) “a priori” individual χ^i for specific experiments.
- ❖ An a posteriori χ'^2 significantly larger than one.
- ❖ Presence of negative (unphysical) cross section after adjustment.
- ❖ Adjustments of cross sections resulting in variations larger than one initial standard deviation.

Covariance Matrix Validation

- ❖ Observation of large difference among well-established covariance matrices (e. g. previously shown for the ^{239}Pu fission). This is the most complicated case, as it can generate harmful compensations.
- ❖ One particular difficult case is to assess if the standard deviation is too large. Likely, some insight can be gained by looking at the $\Delta\chi_{\sigma}^{i2}$ after adjustment.
- ❖ The converse case of determining if the standard deviation is too low could be identified by using an elemental experiment focused on the considered cross section and looking if after adjustment a variation larger than more than one initial standard deviation has been observed

Use of “A Posteriori” Covariance Matrix

- ❖ Most of the “a priori” covariance matrix validation criteria turn around standard deviations. The same can be said for the use of the “a posteriori” covariance matrix. Solid conclusions can be made on the standard deviations, but very little can be assumed for the correlations.
- ❖ The first consequence of the adjustment is that the “a posteriori” correlation matrix is full. Are the new correlations useful and have they a physical meaning?
Yes they are useful, and, possibly, they are physical.
- ❖ The new created correlations are not too large in magnitude but sufficient to have a significant impact in reducing the “a posteriori” uncertainty
- ❖ The current opinion among experts is that the sensitivity coefficients detect and establish these correlations and, therefore, there is, likely, a physical meaning associated to them.

Problems with negative eigenvalues in covariance matrix

- If covariance matrix has zero and/or negative eigenvalues (mostly due to truncations) there are problems:
 - ❖ Difficulty in inverting matrices (both original and adjustment one)
 - ❖ Many multiplications leads to unphysical values (imaginary values of cross section standard deviations)
- Problem found in big adjustment where 75 zero or negative eigenvalues found (1126 cross sections):
 - ❖ Impossible to invert the initial covariance matrix
 - ❖ Imaginary values for standard deviations of 7 cross sections (elastic and inelastic ²³⁵U)
- Possible remedies:
 - ❖ Multiply by a factor all correlations. We had to use 0.8 factor that affects significantly results.
 - ❖ Recalculate matrix by replacing with positive eigenvalues:
 $B=VT'V^{-1}$. Slight impact on results.
 - ❖ Under study: identification of data responsible for negative values through kernel of eigenvalues, then apply factor only to identified cross sections.

Conclusions

- **The role of cross section adjustment has entered a new phase, where the mission is to provide useful feedback not only to designers but directly to evaluators in order to produce improved nuclear data files that will account in a rigorous manner of all experimental information available, both differential and integral.**
- **Criteria have been established for assessing the robustness and reliability of the adjustment:**
 - ❖ **evaluation of consistency, completeness, usefulness, and complementarity of the set of experiments selected for the adjustment**
 - ❖ **criteria provide information on the reliability of the experimental uncertainties, the correlation among experiments and hints on possible yet undetected systematic errors**
 - ❖ **criteria for accepting the “a posteriori” cross sections**
 - ❖ **identifications and elimination of possible compensation effects coming from missing experiments, isotopes, reactions, and unreliability of the covariance matrix**

Conclusions

- **Once** the adjustment is deemed to be dependable, many conclusions can be drawn on the reliability of the adopted covariance matrix and feedback, therefore, can be provided mostly on standard deviations and, at a somewhat more limited extent, on the “a priori” correlation values among nuclear data.
- Some indications of the use of the “a posteriori” covariance matrix have been provided, even though more investigation is needed to settle this complex subject.
